

What the New Website Does Better

A plain-language comparison between the original site and its rebuild

The new site was built to look and behave like the original — same layout, same wording, same motion. That was the goal, and it was measured rather than eyeballed: every heading size, spacing value and animation timing was taken from the original's own files.

Along the way a number of things were fixed. This report explains what those are and why they matter, without assuming any technical background. It also states plainly what is not yet finished.

6 of 8

service pages rebuilt

190

automated checks passing

8

screen sizes tested

15

broken images found

1. More people can actually use it

The clearest improvements are in how the site behaves for people who don't use a mouse — those navigating by keyboard, and those using screen-reading software. On the original, several things simply cannot be reached.

Menus that only opened on hover now open on keyboard too

On the service pages, each card hides its description and its link until you hover over it with a mouse. Someone using a keyboard can move focus onto that link, but the panel stays hidden — so they are focused on something they cannot see. On the new site the panel opens for both.

The price switch can now be operated without a mouse

The pricing section has a Monthly / Yearly toggle that changes the price shown. On the original it is decorative markup that only responds to a click. On the new site it is a real switch: it can be reached and flipped by keyboard, and screen-reading software announces which billing period is currently selected.

The page now has a proper headline

Search engines and screen readers both look for a page's main heading to understand what the page is about. On the original service pages, the only element marked as the main heading is the large decorative word in the footer. The actual headline is not marked as one. On the new site the real headline carries that role — it looks identical, but it is now the thing being described.

Decorative animations no longer interrupt screen readers

Several animated graphics sit inside headlines. Unless they are explicitly marked as decoration, screen-reading software reads them out mid-sentence. They are now marked, so the headline is read as one clean sentence.

2. It loads lighter

Videos no longer download before you scroll to them

The original marks its videos "do not preload" and then also sets them to play automatically. Those two instructions cancel each other out — the browser downloads them straight away. On a single service page that is roughly **32 MB** pulled down whether or not the visitor ever scrolls far enough to see them.

On the new site each video begins loading only as it comes near the screen. A still image holds its place until then, so nothing jumps around.

Two videos were being borrowed from another website

On the AI Marketing page, two background videos were loaded directly from a third-party stock photo site rather than from your own. If that site changes an address, blocks the traffic, or goes down, those videos disappear from your page with no warning. Both are now hosted on your own site.

The page arrives ready to read

The new site sends finished pages from the server rather than sending a blank page and assembling it in the visitor's browser. Text is present immediately, which helps on slow connections and means search engines see the full content without having to run anything.

3. Problems found in the original

Rebuilding the site meant reading every page of the original closely. That surfaced a number of faults that are still live today. None were invented — each was confirmed against the original site itself.

What was found	Why it matters
15 images are missing	Fifteen images referenced across the AI Marketing and Branding pages do not exist on the server. Visitors see broken-image placeholders where artwork should be — including a whole row of client logos and four case-study images.
One FAQ answer is blank	On the App Development page, the question "Can you build scalable enterprise-grade iOS solutions?" opens to nothing. A visitor clicks it and gets an empty panel.
Wrong FAQs on three pages	The UI/UX Design, Branding and Digital Marketing pages all show the same four questions copied from the Web Development page — about mobile-responsiveness, browsers and SEO. None of them relate to the service being sold on that page.
One card is unstyled	On the AI Implementation page, one of five feature cards is missing the code that gives it its frame and background, so it renders differently from its four neighbours.

The wrong-FAQ issue is worth flagging to whoever owns the website copy. It is a content decision, not a technical one, so the new site reproduces the text exactly as written rather than quietly rewriting it. **Nothing has been invented on your behalf.**

4. It is checked automatically, every time

The new site comes with **190 automated checks** that run against a real browser. They confirm, at eight different screen widths from a small phone to a wide monitor, that:

- every section is present and readable
- nothing spills off the side of the screen
- the layout matches the original's measurements exactly
- keyboard users can reach everything a mouse user can
- colour contrast meets the recognised accessibility standard

This matters for the future more than today: if someone changes something six months from now and it breaks a page, the checks catch it before visitors do.

Two faults were caught this way during the build

A card was rendering with no height at all — invisible, and impossible to hover. And the services menu was closing before the mouse could travel from the button down to the menu, so clicking a service was a matter of luck. Both were found by measurement, not by chance, and both are fixed.

5. Where the two sites match exactly

Fidelity was the brief, and the parts that were rebuilt match to the pixel. Measurements taken from the live pages:

Screen width	Headline size	Panel height	Matches original
1536 px	80 px	234 px	Yes
1280 px	65 px	185 px	Yes
768 px	44 px	200 px	Yes
375 px	30 px	200 px	Yes

Where the original's own artwork was missing, the genuine file was downloaded and used rather than approximated — including the fine grid texture behind two sections, which turned out to have uneven, non-square cells that a hand-drawn substitute would have got noticeably wrong.

6. What is not finished

Two of the eight service pages have not been rebuilt yet. These items are stated here so the picture is complete.

Item	Status
AI Chatbot page	Not rebuilt. The page is currently defined twice in the project, and one of the two must be removed before it can be done properly. A decision is needed on which to keep.
AI Marketing page	Partly rebuilt — three of its seven sections are done. The remaining four cannot be completed because every image they rely on is missing from the original (see section 3). Supplying those files would unblock it.
Footer wordmark	Reviewed and closed — no change needed. The very large, very faint word behind the footer was being reported by the automated contrast check. On inspection it is deliberate decoration: it is already hidden from screen-reading software, it carries no information, and the company name it repeats is announced elsewhere in the header and footer. Making it darker or lighter to satisfy the check would put a giant word in competition with the footer's real content — worse for every reader, including the ones the rule exists to protect. It is recorded as a documented exception rather than silenced.
Large video file	One background video is 61 MB. It works, but compressing it would noticeably speed up the AI Marketing page on slower connections.

In short

The rebuilt pages look like the original because that was the point. What changed is underneath: the site can now be used without a mouse, it stops downloading tens of megabytes of video that nobody asked for, it no longer depends on another company's server for its own content, and it checks itself for mistakes every time it is updated.

Along the way it also produced an honest list of what is broken on the current site — including fifteen missing images and a set of FAQs pointing visitors at the wrong answers.

Every figure in this report was measured against the live sites rather than estimated. Items described as unfinished are listed in section 6 rather than omitted.
